1 Pseudofinite yoga

As a matter of personal taste I have avoided the use of ultrapowers to deal with pseudofinite structures. Also, I have avoided the notion of pseudofinite dimension, as it is too general for the intended applications.

For convenience, all finite models considered below have as domain a subset of ω . We say that a sentence holds in almost all finite models if it holds in every finite model of sufficiently large cardinality.

Let T_0 be a given theory with arbitrarily large finite models. We define

$$T_{\text{fin}} = \{ \varphi : M \vDash \varphi \text{ for almost all finite } M \vDash T_0 \}.$$

A structure N is a pseudofinite model of T_0 if $N \models T_{\text{fin}}$. This is equivalent to requiring that every sentence $\varphi \in \text{Th}(N)$ there holds in arbitrarily large finite models of T_0 . Note that every model of T_{fin} is infinite. (Other authors include in T_{fin} only sentences true in *all* finite models. Hence they include the finite models among the pseudofinite ones.)

We now discribe a canonical expansion of a finite model M to a two sorted structure $\langle M, \mathbb{N} \rangle$. The language of $\langle M, \mathbb{N} \rangle$ is denoted by L'.

- 1. L' expands the language of M and \mathbb{N} , where \mathbb{N} is considered as a structure in the language with symbols for all real relations and functions of any finite arity.
- 2. L' has a function $f_{\varphi}: M^{|z|} \to \mathbb{N}$ for each formula $\varphi(x;z) \in L'$ and every finite tuples of variables x;z of the first sort. The interpretation of $f_{\varphi}(b)$ is the (finite) cardinality of $\varphi(M;b)$.
- 3. (Only reqired in Section 2.) Let X be an n-ary relation symbol of the first sort. Let $\varphi \in L \cup \{X\}$ be a sentence. Then we require that L' has an n-ary predicate A_{φ} in the first sort. The interpretation of A_{φ} is a relation of maximal cardinality that makes φ true in M. If more then one relation satisfy the requirement above, we choose the minimal one in the lexicographic order (recall that the domain of M is a subset of ω).

Finally, we define

$$T'_{\text{fin}} = \{ \varphi \in L' : \langle M, \mathbb{N} \rangle \vDash \varphi \text{ for all finite } M \vDash T_0 \}.$$

In the sequel $(\mathcal{U}, *\mathbb{N})$ denotes some arbitrary saturated model of T'_{fin} .

1 Fact Assume that $\psi \in L'$ holds in every $\langle \mathcal{U}, {}^*\mathbb{N} \rangle$ as above. Then $\langle M, \mathbb{N} \rangle \models \psi$ for all sufficiently large finite $M \models T_0$.

Below we write $*|\varphi(x;b)|$ for $f_{\varphi}(b)$. We call this the pseudofinite cardinality of $\varphi(x;b)$. By the definition of T'_{fin} it is clear that the pseudofinite cardinality of a definable set \mathcal{D} does not depend on the formula defining it, so we can unambiguously write $*|\mathcal{D}|$.

For $r, s \in {}^*\mathbb{N}$ larger than 1 we write $r \curvearrowright s$ if $r \le ms$ and $s \le nr$ for some $m, n \in \mathbb{N}$. We write $r \curvearrowright s$ if $r \le s^m$ and $s \le r^n$ for some $m, n \in \mathbb{N}$. We write $r \curvearrowright s$ and $r \not \curvearrowright s$ if n < s, respectively $r^n < s$ for all $n \in \mathbb{N}$.

2 Proposition Let \sim denote either γ or γ . For every non negative $r, s \in {}^*\mathbb{N}$

$$r + s \sim \max\{r, s\}$$

In particular, if $\mathcal{D}, \mathcal{C} \subseteq \mathcal{U}^z$ are two definable sets, then

$$*|\mathcal{D} \cup \mathcal{C}| \sim \max\{*|\mathcal{D}|, *|\mathcal{C}|\}.$$

Proof In fact

$$\max\{r,s\} \leq r+s$$

$$\leq 2\max\{r,s\}$$

$$\leq (\max\{r,s\})^2$$

This proves the first equivalence. The second equivalence follows.

Definable sets $\mathcal{D} \subseteq \mathcal{U}^x$ such that $*|\mathcal{D}| \sim *|\mathcal{U}^x|$ are called large, otherwise we say they are small. The context will clarify if we are referring to the linear or to the polynomial equivalence.

3 Corollary Let \sim denote either γ or γ . Let $p(x) \subseteq L(M)$ be a type such that $\varphi(\mathfrak{U})$ is large for every $\varphi(x)$ that is conjunction of formulas in p(x). Then p(x) has an extension to a complete type with the same property.

The following fact is immediate. It is stated to illustrate the typical application of the notions introduced above.

4 Fact Let \sim denote either γ or γ . Let $\varphi(x;z) \in L$, where x has finite length. Assume that in every model $\langle \mathcal{U}, {}^*\mathbb{N} \rangle$ there is a $b \in \mathcal{U}^z$ such that $\varphi(\mathcal{U}^x;b)$ is large. Then there is an $n \in \mathbb{N}$ such that every sufficiently large finite $M \models T_0$ contains a tuple c such that

$$\left|M^{x}\right| \leq n \left|\varphi(M^{x};c)\right| \quad \text{if } \sim \text{is } \gamma$$

$$\left|M^{x}\right| \leq \left|\psi(M^{x};c)\right|^{n} \quad \text{if } \sim \text{is } \gamma.$$

The following two proposition only hold for \sim .

5 Proposition For every non negative $r, s \in {}^*\mathbb{N}$

$$r \cdot s \approx \max\{r, s\}$$

Proof In fact

$$\max\{r,s\} \leq r \cdot s$$

$$\leq \left(\max\{r,s\}\right)^2 \qquad \Box$$

Note that, in particular, $*|\mathcal{U}| > *|\mathcal{U}^x|$ for all tuples of variables of finite arity.

6 Corollary Let $\psi(x,z) \in L'$, where x,z are finite tuples of variables of the first sort. Let $A \subseteq \mathcal{U}$. Assume that

$$*|\mathcal{A}| \leq *|\mathcal{U}|$$
 $*|\psi(a,\mathcal{U}^z)| \leq *|\mathcal{U}| \text{ for every } a \in \mathcal{A}.$

Then

$$\left\| \bigcup_{a \in \mathcal{A}} \psi(a, \mathcal{U}^z) \right\| \leq \left\| \mathcal{U} \right\|.$$

Proof Let $r = *|\mathcal{A}|$. Let $s = *|\psi(a,z)|$, where $a \in \mathcal{A}$ is choosen such that s is maximal. Then

$$\begin{vmatrix}
* \middle| \bigcup_{a \in \mathcal{A}} \psi(a, \mathcal{U}^z) \middle| & \leq r \cdot s \\
& \leq * |\mathcal{U}| \cdot * |\mathcal{U}| \\
& \approx * |\mathcal{U}|.
\end{vmatrix}$$

2 Erdős-Hajnal for stable graphs

Let $r(\cdot, \cdot)$ be a binary relation symbol. The theory that T_0 says that $r(\cdot, \cdot)$ is an irreflexive and symmetric relation (i.e. a graph) and that it is m-stable, where m is fixed but arbitrary. For the purpose of these notes m-stable means that $R_{\Delta}(\mathcal{U}) \leq m$, where R_{Δ} is defined below.

Let $\Delta = \{r(a,x) : a \in \mathcal{U}\}$. Let $S \subseteq \mathcal{U}$. We denote by $R_{\Delta}(S)$ the Shelah binary rank of S. That is, the maximal height n of binary tree of Δ^{\pm} -formulas $\langle \varphi_i(x) : s \in {}^{< n} 2 \rangle$ such that for every $s \in {}^{n} 2$ the type

$$\left\{\neg^{s_i} \varphi_{s \upharpoonright i}(x) : i \le n\right\}$$

has a solution in S.

As T_0 is stable, $R_{\Delta}(\mathcal{U})$ is finite. Among the large $L(\mathcal{U})$ -definable subsets of \mathcal{U} we fix one, say $\mathcal{S} = \sigma(\mathcal{U})$, such that $R_{\Delta}(\mathcal{S})$ is minimal.

7 Fact For every Δ^{\pm} -definable set $\mathcal{D} \subseteq \mathcal{U}$, exactly one between $\mathcal{S} \cap \mathcal{D}$ and $\mathcal{S} \cap \neg \mathcal{D}$ is large.

Proof As S is large, at least one between $S \cap D$ and $S \cap \neg D$ is large by Proposition 2. Now, suppose for a contradiction that they both are large. Let $n = R_{\Delta}(S)$. By the minimality of n, both $S \cap D$ and $S \cap \neg D$ have rank n. This contradicts the definition of rank.

8 Theorem There is a large set $A \subseteq \mathcal{U}$ that is either a clique or an anticlique.

Proof Let $S = \sigma(\mathcal{U})$ be as defined above. Let $p(x) \subseteq \Delta^{\pm}$ be maximally consistent among the Δ^{\pm} -types such that $\sigma(x) \wedge \varphi(x)$ is large for every conjunction of formulas in the type. By the fact above, p(x) is Δ^{\pm} -complete, i.e. either $\varphi(x)$ or $\neg \varphi(x)$ is in p(x) for every $\varphi(x) \in \Delta^{\pm}$.

Let $\mathcal{B} = \{a \in \mathcal{S} : r(a,x) \in p\}$. By stability, \mathcal{B} is definable in $L(\mathcal{U})$. At least one between \mathcal{B} and $\mathcal{S} \setminus \mathcal{B}$ is large. Assume the first, the argument when $\mathcal{S} \setminus \mathcal{B}$ is large is similar.

Let \mathcal{A} be a definable subsets of \mathcal{B} that is maximal among those that satisfy the formula $(\forall x, y \in \mathcal{A}) r(x, y)$. The definition of L' guarantees that such a set exists.

We claim that A is large, hence it is the clique required by the theorem. So, assume not, and reason for a contradiction.

By the maximality of \mathcal{A} , for every $b \in \mathcal{B} \setminus \mathcal{A}$ there is an $a \in \mathcal{A}$ such that $\neg r(a,b)$. We rephrase this as the inclusion

$$\mathcal{B} \setminus \mathcal{A} \subseteq \bigcup_{a \in \mathcal{A}} \neg r(a, \mathcal{S})$$

By assumption \mathcal{A} is not large, hence $\mathcal{B} \setminus \mathcal{A}$ is large. When $a \in \mathcal{A}$, in particular $r(a,x) \in p$. Therefore, by the fact above, $r(a,\mathcal{S})$ is large and $\neg r(a,\mathcal{S})$ is small. This is a contradiction by Corollary 6.

Finally the Erdős-Hajnal property is obtained applying Fact 4.

9 Corollary There is an n such that in every finite model $M \models T_0$ there is a set $A \subseteq M$ of cardinality at least $|M|^{1/n}$ that is either a clique or an anticlique.

3 Pseudofinite counting measure

Below, the theory T_0 , the set of formulas Δ , and the rank $m = R_{\Delta}$ are as defined the provious section.

Let $\mathcal{D} \subseteq \mathcal{U}$ be a definable set. We define

$$\mu(\mathcal{D}) = \inf \left\{ \frac{m}{n} : m, n \in \mathbb{N} \setminus \{0\} \text{ such that } n^* |\mathcal{D}| \le m^* |\mathcal{U}| \right\},$$

where the infimum is taken in \mathbb{R} . It is immediate that $\mu(-)$ is a finite probability measure on the definable subsets of \mathcal{U} . (By the Caratheodory Theorem it can be extended to a probability measure but this is not required here.)

We will write $A =_{\mu} D$ if $\mu(A \triangle D) = 0$.

10 Lemma There are some pairwise disjoint $\{\wedge\}\Delta^{\pm}$ -definable sets $\mathcal{B}_0, \ldots, \mathcal{B}_{n-1} \subseteq \mathcal{U}$, where $n \leq 2^m$, such that for any $\{\wedge\vee\neg\}\Delta$ -definable set \mathcal{A} ,

$$\mathcal{A} =_{\mu} \bigcup_{i \in I} \mathcal{B}_i$$

Per qualche $I \subseteq n$. Finally, we can require that all \mathcal{B}_i have positive measure.

Proof We prove a slightly more general claim. For any definable set \mathcal{D} of positive measure let $\mu_{\mathcal{D}}$ be the contitional measure:

$$\mu_{\mathcal{D}}(\mathcal{A}) = \mu(\mathcal{A}|\mathcal{D})$$

$$= \frac{\mu(\mathcal{A} \cap \mathcal{D})}{\mu(\mathcal{D})}$$

We prove by induction on $R_{\Delta}(\mathcal{D}) = m$ that there are $n \leq 2^m$ many $\{\wedge\}\Delta^{\pm}$ -definable sets \mathcal{B}_i such that

$$\mathcal{A} =_{\mu} \bigcup_{i \in I} \mathcal{B}_i$$

For some $I \subseteq n$. Clearly it suffices to consider $A \subseteq \mathcal{D}$ that are $\{\wedge\}\Delta^{\pm}$ -definable.

If $R_{\Delta}(\mathcal{D}) = 0$ then \mathcal{D} is either disjoint of contained in every Δ^{\pm} -definable set. So the claim holds trivially.

Now, let $R_{\Delta}(\mathcal{D}) = m + 1$. By the definition of binary rank, there is a Δ -definable set \mathcal{B} such that $R_{\Delta}(\mathcal{D} \cap \mathcal{B}) = R_{\Delta}(\mathcal{D} \cap \neg \mathcal{B}) = m$. Apply the induction hypothesis to $\mathcal{D} \cap \mathcal{B}$ if it has positive measure. Do the same for $\mathcal{D} \cap \neg \mathcal{B}$. Note that at least one has positive measure.

Non sono sicuro questa sia la corretta traduzione finita.

11 Corollary For every $\varepsilon > 0$ there is an k such that for every finite $M \vDash T_0$ of cardinality larger than k, there are some disjoint sets $B_0, \ldots, B_{n-1} \subseteq M$, where $n \le 2^m$

and $\mu(B_i) > \varepsilon$, such that for every $\{\land \lor \neg\}\Delta$ -definable set $A \subseteq M$ there is an $I \subseteq n$ such that

$$\varepsilon > \mu \left(A \triangle \bigcup_{i \in I} B_i \right).$$

4 Stable Szemerédi regularity lemma

Below, the theory T_0 , the set of formulas Δ , and the rank $m = R_{\Delta}$ are as defined in Section 2.

12 Lemma There are two partitions of \mathcal{U} , say $\mathcal{B}_0, \ldots, \mathcal{B}_n$, where $n \leq 2^m$, and $\mathcal{C}_1, \ldots, \mathcal{C}_{2^n}$ such that for all i, j either $r(\mathcal{B}_i, \mathcal{C}_j) =_{\mu} \emptyset$ or $r(\mathcal{B}_i, \mathcal{C}_j) =_{\mu} \mathcal{B}_i \times \mathcal{C}_j$.

Proof Let $\mathcal{B}_0, \ldots, \mathcal{B}_{n-1}$ be the sets given by Lemma 10 and define

$$\mathcal{B}_n = \mathcal{U} \setminus \bigcup_{i=0}^{n-1} \mathcal{B}_i.$$

For every $J \subseteq n$ let

$$\mathcal{C}_J = \left\{ c \in \mathcal{U} : \bigcup_{i \in J} \mathcal{B}_i =_{\mu} r(\mathcal{U}, c) \right\}$$

By Lemma 10 if $i \in J$ then $r(\mathcal{B}_i, \mathcal{C}_I) =_{\mu} \mathcal{B}_i \times \mathcal{C}_I$, otherwise $r(\mathcal{B}_i, \mathcal{C}_I) =_{\mu} \emptyset$.

It is only left to verify the lemma for $r(\mathcal{B}_n, \mathcal{C}_J)$. Indeed, as $\mathcal{B}_n =_{\mu} \emptyset$ by Lemma 10, we have that $r(\mathcal{B}_n, \mathcal{C}_J) \subseteq \mathcal{B}_n \times \mathcal{U} =_{\mu} \emptyset$.

Finally, the the stable Szemerédi regularity lemma is obtained applying Fact 4.

13 Corollary For every $\varepsilon > 0$ there is an k such that for every finite $M \vDash T_0$ of cardinality larger than k, there are two partitions of M, say B_0, \ldots, B_n , where $n \le 2^m$, and C_1, \ldots, C_{2^n} , such that one of the following obtains

$$|r(B_i, C_j)| \le \varepsilon |B_i \times C_j|$$

 $|r(B_i, C_j)| \ge (1 - \varepsilon) |B_i \times C_j|.$
